- These approaches were unified by M. Karchmer with his "Fusion method"

## Some context

- goal: Lower bounds (ideally) on non-monotone circuits
- so far we've seen:
- Razborov's approximation method
- Sipser's topological approach
- These approaches were unified by M. Karchmer with his "Fusion method"
- we will cover the survey article: Avi Widgerson - The Fusion Method for Lower Bounds in Circuit Complexity

## General idea

Lower bound for a boolean function $\rightarrow$ Combinatorial "covering" problem

## General idea

Lower bound for a boolean function $\rightarrow$ Combinatorial "covering" problem

- Ultraproduct

## General idea

Lower bound for a boolean function $\rightarrow$ Combinatorial "covering" problem

- Ultraproduct
- We have a collection $\left(\mathcal{A}_{i}, i \in I\right)$ of structures, $\mathcal{A}_{i} \models T$.

## General idea

Lower bound for a boolean function $\rightarrow$ Combinatorial "covering" problem

- Ultraproduct
- We have a collection $\left(\mathcal{A}_{i}, i \in I\right)$ of structures, $\mathcal{A}_{i} \models T$.
- If we have an ultrafilter $\mathcal{U}$ on $I$. We can form a new structure

$$
\prod_{i \in I} \mathcal{A}_{i} / \mathcal{U} \vDash T .
$$

## General idea

Lower bound for a boolean function $\rightarrow$ Combinatorial "covering" problem

- Ultraproduct
- We have a collection $\left(\mathcal{A}_{i}, i \in I\right)$ of structures, $\mathcal{A}_{i} \models T$.
- If we have an ultrafilter $\mathcal{U}$ on I. We can form a new structure

$$
\prod_{i \in I} \mathcal{A}_{i} / \mathcal{U} \vDash T .
$$

- Fusing computations

## General idea

Lower bound for a boolean function $\rightarrow$ Combinatorial "covering" problem

- Ultraproduct
- We have a collection $\left(\mathcal{A}_{i}, i \in I\right)$ of structures, $\mathcal{A}_{i} \models T$.
- If we have an ultrafilter $\mathcal{U}$ on $I$. We can form a new structure

$$
\prod_{i \in I} \mathcal{A}_{i} / \mathcal{U} \models T
$$

- Fusing computations
- We have some program $P$, accepting exactly $U \subseteq\{0,1\}^{n}$, and for each $u \in U$, we have $P(u)$ an accepting computation of $u$.

## General idea

Lower bound for a boolean function $\rightarrow$ Combinatorial "covering" problem

- Ultraproduct
- We have a collection $\left(\mathcal{A}_{i}, i \in I\right)$ of structures, $\mathcal{A}_{i} \models T$.
- If we have an ultrafilter $\mathcal{U}$ on $I$. We can form a new structure

$$
\prod_{i \in I} \mathcal{A}_{i} / \mathcal{U} \models T
$$

- Fusing computations
- We have some program $P$, accepting exactly $U \subseteq\{0,1\}^{n}$, and for each $u \in U$, we have $P(u)$ an accepting computation of $u$.
- If we have some finite analogue of an ultrafilter $F$, we can fuse them into a new "accepting computation" of some new $z$, a contradiction.

## Straight-line programs, computations

## Definition

Let $X=\left\{x_{1}, \ldots, x_{k}\right\}$ be a set of variables. $A$ straight-line program $P$ is a tuple $\left(g_{1}, \ldots, g_{t}\right)$, such that $g_{i}=x_{i}$ for $i \in\{0, \ldots, n\}$ and $g_{i}=g_{i_{1}} \circ_{i} g_{i_{2}}$ where $i_{1}, i_{2}<i$, and $\circ_{i} \in O P$ some set of binary operations. For $u \in\{0,1\}^{n}$ we define a computation of $P$ on input $u$ as $P(u):=\left(g_{1}(u), \ldots, g_{t}(u)\right)$, where $g_{t}(u) \in\{0,1\}$ is the output of the computation.

## An example of a straight-line program

- Consider the circuit:

## An example of a straight-line program

- Consider the circuit:

- The corresponding straight-line program is

$$
P=\left(x_{1}, x_{2}, x_{3}, x_{1} \vee x_{2},\left(x_{1} \vee x_{2}\right) \wedge x_{3}\right) .
$$

## An example of a straight-line program

- Consider the circuit:

- The corresponding straight-line program is

$$
P=\left(x_{1}, x_{2}, x_{3}, x_{1} \vee x_{2},\left(x_{1} \vee x_{2}\right) \wedge x_{3}\right) .
$$

- And the following is an accepting computation of $P(1,0,1)$

$$
P(1,0,1)=(1,0,1,1,1)
$$

## The fusion method

- Let $U \subseteq\{0,1\}^{n}$, we would like to find a lower bound on the length of the shortest straight-line program accepting exactly $U$.

## The fusion method

- Let $U \subseteq\{0,1\}^{n}$, we would like to find a lower bound on the length of the shortest straight-line program accepting exactly $U$.
- This is equivalent to finding a lower bound for a straight-line program computing some boolean function $f$ on $n$-letter strings by setting $U=f^{-1}[1]$.

## The fusion method

- Let $U \subseteq\{0,1\}^{n}$, we would like to find a lower bound on the length of the shortest straight-line program accepting exactly $U$.
- This is equivalent to finding a lower bound for a straight-line program computing some boolean function $f$ on $n$-letter strings by setting $U=f^{-1}[1]$.
- Assume for contradiction there exists some program $P=\left(g_{1}, \ldots, g_{t}\right)$ that accepts exactly $U$ and $t$ is too small.

## The accepting computation matrix

- Consider a $|U| \times t$ matrix, where rows are indexed by $U$ and each row is equal to the computation $P(u)$.

| $u$ |  |  |  |  | the rest of $P(u)$ |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | $\ldots$ | 0 | 1 | 0 | 1 | $\ldots$ | 0 | 1 |
| 0 | 0 | $\ldots$ | 1 | 1 | 0 | 0 | $\ldots$ | 0 | 1 |
| 1 | 0 | $\ldots$ | 0 | 1 | 1 | 0 | $\ldots$ | 1 | 1 |
| 1 | 0 | $\ldots$ | 1 | 0 | 1 | 0 | $\ldots$ | 1 | 1 |
| $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |
| 1 | 1 | $\ldots$ | 1 | 0 | 0 | 0 | $\ldots$ | 0 | 1 |

## Producing a contradiction

| $u$ |  |  |  | the rest of $P(u)$ |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | $\ldots$ | 0 | 1 | 0 | 1 | $\ldots$ | 0 | 1 |
| 0 | 0 | $\ldots$ | 1 | 1 | 0 | 0 | $\ldots$ | 0 | 1 |
| 1 | 0 | $\ldots$ | 0 | 1 | 1 | 0 | $\ldots$ | 1 | 1 |
| 1 | 0 | $\ldots$ | 1 | 0 | 1 | 0 | $\ldots$ | 1 | 1 |
| $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |
| 1 | 1 | $\ldots$ | 1 | 0 | 0 | 0 | $\ldots$ | 0 | 1 |

- We would like to produce a contradiction using that the number of rows $t$ is too small.

## Producing a contradiction

| $u$ |  |  |  | the rest of $P(u)$ |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | $\ldots$ | 0 | 1 | 0 | 1 | $\ldots$ | 0 | 1 |
| 0 | 0 | $\ldots$ | 1 | 1 | 0 | 0 | $\ldots$ | 0 | 1 |
| 1 | 0 | $\ldots$ | 0 | 1 | 1 | 0 | $\ldots$ | 1 | 1 |
| 1 | 0 | $\ldots$ | 1 | 0 | 1 | 0 | $\ldots$ | 1 | 1 |
| $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |
| 1 | 1 | $\ldots$ | 1 | 0 | 0 | 0 | $\ldots$ | 0 | 1 |

- We would like to produce a contradiction using that the number of rows $t$ is too small.
- We will try to construct a "new" accepting computation using the old ones. Since this table contains all accepting computations, this would be a contradiction.

## Fusing the computations

- How to produce the new computation?

## Fusing the computations

- How to produce the new computation?
- Let $F:\{0,1\}^{|U|} \rightarrow\{0,1\}$, "a functional" from some set $\Omega$ of functionals (will be specified later, e.g. $\Omega=\{$ all functionals $\}$ works).

## Fusing the computations

- How to produce the new computation?
- Let $F:\{0,1\}^{|U|} \rightarrow\{0,1\}$, "a functional" from some set $\Omega$ of functionals (will be specified later, e.g. $\Omega=\{$ all functionals $\}$ works).
- $F$ will act as our finite analogue of an ultrafilter.

## Applying the functional

| 0 | 1 | $\ldots$ | 0 | 1 | 0 | 1 | $\ldots$ | 0 | 1 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | $\ldots$ | 1 | 1 | 0 | 0 | $\ldots$ | 0 | 1 |
| 1 | 0 | $\ldots$ | 0 | 1 | 1 | 0 | $\ldots$ | 1 | 1 |
| 1 | 0 | $\ldots$ | 1 | 0 | 1 | 0 | $\ldots$ | 1 | 1 |
| $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |
| 1 | 1 | $\ldots$ | 1 | 0 | 0 | 0 | $\ldots$ | 0 | 1 |

| $\downarrow_{F}$ |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0 |  |  |  |  |  |

## Applying the functional

| 0 | 1 |  | 0 | 1 |  | 0 | 1 | .. | 0 |  |  |

## Requirements on the functional

- It is obvious there is no guarantee that the resulting tuple will be an accepting computation.

## Requirements on the functional

- It is obvious there is no guarantee that the resulting tuple will be an accepting computation.
- By $F\left(g_{i}\right)$ we mean the output of $F$ on $i$-th column of the accepting computation matrix.

## Requirements on the functional

- It is obvious there is no guarantee that the resulting tuple will be an accepting computation.
- By $F\left(g_{i}\right)$ we mean the output of $F$ on $i$-th column of the accepting computation matrix.
- There are three requirements on the functional $F$ for this to work:

## Requirements on the functional

- It is obvious there is no guarantee that the resulting tuple will be an accepting computation.
- By $F\left(g_{i}\right)$ we mean the output of $F$ on $i$-th column of the accepting computation matrix.
- There are three requirements on the functional $F$ for this to work:
(1) $F$ "encodes" some $z \notin U$, that is, $F\left(g_{i}\right)=z_{i}$ for $i \in\{1, \ldots, n\}$ (the " $u$ " part of the new row is $z$ )

## Requirements on the functional

- It is obvious there is no guarantee that the resulting tuple will be an accepting computation.
- By $F\left(g_{i}\right)$ we mean the output of $F$ on $i$-th column of the accepting computation matrix.
- There are three requirements on the functional $F$ for this to work:
(1) $F$ "encodes" some $z \notin U$, that is, $F\left(g_{i}\right)=z_{i}$ for $i \in\{1, \ldots, n\}$ (the " $u$ " part of the new row is $z$ )
(2) The resulting computation is accepting, that is $F(\overline{1})=1$

## Requirements on the functional

- It is obvious there is no guarantee that the resulting tuple will be an accepting computation.
- By $F\left(g_{i}\right)$ we mean the output of $F$ on $i$-th column of the accepting computation matrix.
- There are three requirements on the functional $F$ for this to work:
(1) $F$ "encodes" some $z \notin U$, that is, $F\left(g_{i}\right)=z_{i}$ for $i \in\{1, \ldots, n\}$ (the " $u$ " part of the new row is $z$ )
(2) The resulting computation is accepting, that is $F(\overline{1})=1$
(3) $F$ is consistent, that is $F\left(g_{i_{1}}\right) \circ_{i} F\left(g_{i_{2}}\right)=F\left(g_{i_{1}} \circ_{i} g_{i_{2}}\right)$ for $n<i \leq t$

## Requirements on the functional

- It is obvious there is no guarantee that the resulting tuple will be an accepting computation.
- By $F\left(g_{i}\right)$ we mean the output of $F$ on $i$-th column of the accepting computation matrix.
- There are three requirements on the functional $F$ for this to work:
(1) $F$ "encodes" some $z \notin U$, that is, $F\left(g_{i}\right)=z_{i}$ for $i \in\{1, \ldots, n\}$ (the " $u$ " part of the new row is $z$ )
(2) The resulting computation is accepting, that is $F(\overline{1})=1$
(3) $F$ is consistent, that is $F\left(g_{i_{1}}\right) \circ_{i} F\left(g_{i_{2}}\right)=F\left(g_{i_{1}} \circ_{i} g_{i_{2}}\right)$ for $n<i \leq t$
- We will search for such $F$ by considering

$$
\Omega_{f}=\{F \in \Omega ; F \text { satisfies the first two points }\} .
$$

## Requirements on the functional cont.

- We will search for such $F$ by considering

$$
\Omega_{f}=\{F \in \Omega ; F \text { satisfies the first two points }\} .
$$

## Requirements on the functional cont.

- We will search for such $F$ by considering

$$
\Omega_{f}=\{F \in \Omega ; F \text { satisfies the first two points }\} .
$$

- How do we find functional in $\Omega_{f}$ that satisfies the third requirement, since it depends on $P$ ?

## Requirements on the functional cont.

- We will search for such $F$ by considering

$$
\Omega_{f}=\{F \in \Omega ; F \text { satisfies the first two points }\} .
$$

- How do we find functional in $\Omega_{f}$ that satisfies the third requirement, since it depends on $P$ ?
- We don't! We just conclude that if such short $P$ exists, there has to be no such functional in $\Omega_{f}$.

## Covering

## Definition

Let $O P$ be some set of operations. We say, that the triple $(g, h, \circ)$, $g, h \in\{0,1\}^{n} \rightarrow\{0,1\}, \circ \in O P$ covers a functional $F$, if

$$
F(g) \circ F(h) \neq F(g \circ h) .
$$

For a function $f:\{0,1\}^{n} \rightarrow\{0,1\}$ we denote $\rho(f)$ the smallest number of such triples that cover $\Omega_{f}$.

## The lower bound

Theorem (Meta-theorem)
$\rho(f)$ is a lower bound on the shortest straight-line program computing $f$ over OP.

## The lower bound

## Theorem (Meta-theorem) <br> $\rho(f)$ is a lower bound on the shortest straight-line program computing $f$ over OP.

## Proof.

Let $P=\left(g_{1}, \ldots, g_{t}\right)$ be a program computing $f$ and $t<\rho(f)$. Since $\left\{\left(g_{i_{1}}, g_{i_{2}}, \circ_{i}\right) ; i \in\{n+1, \ldots, t\}\right\}$ cannot cover $\Omega_{f}$, therefore there does exists $F \in \Omega_{f}$ that is consistent with this program. $F$ then codes a new accepting computation of some $z \notin f^{-1}[1]$, which is a contradiction.

## The lower bound

## Theorem (Meta-theorem) <br> $\rho(f)$ is a lower bound on the shortest straight-line program computing $f$ over OP.

## Proof.

Let $P=\left(g_{1}, \ldots, g_{t}\right)$ be a program computing $f$ and $t<\rho(f)$. Since $\left\{\left(g_{i_{1}}, g_{i_{2}}, \circ_{i}\right) ; i \in\{n+1, \ldots, t\}\right\}$ cannot cover $\Omega_{f}$, therefore there does exists $F \in \Omega_{f}$ that is consistent with this program. $F$ then codes a new accepting computation of some $z \notin f^{-1}[1]$, which is a contradiction.

- The lower bound is actually $n+\rho(f)$.

## The lower bound

## Theorem (Meta-theorem)

$\rho(f)$ is a lower bound on the shortest straight-line program computing $f$ over OP.

## Proof.

Let $P=\left(g_{1}, \ldots, g_{t}\right)$ be a program computing $f$ and $t<\rho(f)$. Since $\left\{\left(g_{i_{1}}, g_{i_{2}}, \circ_{i}\right) ; i \in\{n+1, \ldots, t\}\right\}$ cannot cover $\Omega_{f}$, therefore there does exists $F \in \Omega_{f}$ that is consistent with this program. $F$ then codes a new accepting computation of some $z \notin f^{-1}[1]$, which is a contradiction.

- The lower bound is actually $n+\rho(f)$.
- We can restrict the smallest cover to those covers for which each ( $g, h, \circ$ ) has $g, h$ definable by some straight line program over OP.

## Example - parity

- Let $f\left(x_{1}, x_{2}\right)=\left(x_{1}+x_{2}\right) \bmod 2$, let $\mathrm{OP}=\{\wedge, \vee, \neg\}$.

## Example - parity

- Let $f\left(x_{1}, x_{2}\right)=\left(x_{1}+x_{2}\right) \bmod 2$, let $\mathrm{OP}=\{\wedge, \vee, \neg\}$.
- $\neg$ is not a binary operation but we can define it as $\neg\left(g_{i_{1}}, g_{i_{2}}\right)=\neg g_{i_{1}}$.

## Example - parity

- Let $f\left(x_{1}, x_{2}\right)=\left(x_{1}+x_{2}\right) \bmod 2$, let $\mathrm{OP}=\{\wedge, \vee, \neg\}$.
- $\neg$ is not a binary operation but we can define it as $\neg\left(g_{i_{1}}, g_{i_{2}}\right)=\neg g_{i_{1}}$.
- The accepting computation matrix for any program $P$ is

$$
\begin{array}{l|llll}
\hline P\left(\mathbf{u}_{1}\right): & 0 & 1 & \ldots & 1 \\
P\left(\mathbf{u}_{2}\right): & 1 & 0 & \ldots & 1 \\
\hline
\end{array}
$$

## Example - parity

- Let $f\left(x_{1}, x_{2}\right)=\left(x_{1}+x_{2}\right) \bmod 2$, let $\mathrm{OP}=\{\wedge, \vee, \neg\}$.
- $\neg$ is not a binary operation but we can define it as $\neg\left(g_{i_{1}}, g_{i_{2}}\right)=\neg g_{i_{1}}$.
- The accepting computation matrix for any program $P$ is

| $P\left(\mathbf{u}_{1}\right):$ | 0 | 1 | $\ldots$ | 1 |
| :---: | :---: | :---: | :---: | :---: |
| $P\left(\mathbf{u}_{2}\right):$ | 1 | 0 | $\ldots$ | 1 |

- For $\Omega$ unrestricted, what do we have in $\Omega_{f}$ ? We have:

| $\mathrm{g}:$ | $\mathbf{0}$ | $x_{1}$ | $x_{2}$ | $\mathbf{1}$ |
| :---: | :---: | :---: | :---: | :---: |
| $g\left(\mathbf{u}_{1}\right)$ | 0 | 0 | 1 | 1 |
| $g\left(\mathbf{u}_{2}\right)$ | 0 | 1 | 0 | 1 |
| $F_{1}(g)$ | 0 | 0 | 0 | 1 |
| $F_{2}(g)$ | 0 | 1 | 1 | 1 |
| $F_{3}(g)$ | 1 | 0 | 0 | 1 |
| $F_{4}(g)$ | 1 | 1 | 1 | 1 |

## Example - parity

- Let $f\left(x_{1}, x_{2}\right)=\left(x_{1}+x_{2}\right) \bmod 2$, let $\mathrm{OP}=\{\wedge, \vee, \neg\}$.
- $\neg$ is not a binary operation but we can define it as $\neg\left(g_{i_{1}}, g_{i_{2}}\right)=\neg g_{i_{1}}$.
- The accepting computation matrix for any program $P$ is

| $P\left(\mathbf{u}_{1}\right):$ | 0 | 1 | $\ldots$ | 1 |
| :---: | :---: | :---: | :---: | :---: |
| $P\left(\mathbf{u}_{2}\right):$ | 1 | 0 | $\ldots$ | 1 |

- For $\Omega$ unrestricted, what do we have in $\Omega_{f}$ ? We have:

| $\mathrm{g}:$ | $\mathbf{0}$ | $x_{1}$ | $x_{2}$ | $\mathbf{1}$ |
| :---: | :---: | :---: | :---: | :---: |
| $g\left(\mathbf{u}_{1}\right)$ | 0 | 0 | 1 | 1 |
| $g\left(\mathbf{u}_{2}\right)$ | 0 | 1 | 0 | 1 |
| $F_{1}(g)$ | 0 | 0 | 0 | 1 |
| $F_{2}(g)$ | 0 | 1 | 1 | 1 |
| $F_{3}(g)$ | 1 | 0 | 0 | 1 |
| $F_{4}(g)$ | 1 | 1 | 1 | 1 |

- The rows of the two middle columns have to differ from the first two rows because of requirement 1 .

## Example - parity

- Let $f\left(x_{1}, x_{2}\right)=\left(x_{1}+x_{2}\right) \bmod 2$, let $\mathrm{OP}=\{\wedge, \vee, \neg\}$.
- $\neg$ is not a binary operation but we can define it as $\neg\left(g_{i_{1}}, g_{i_{2}}\right)=\neg g_{i_{1}}$.
- The accepting computation matrix for any program $P$ is

| $P\left(\mathbf{u}_{1}\right):$ | 0 | 1 | $\ldots$ | 1 |
| :---: | :---: | :---: | :---: | :---: |
| $P\left(\mathbf{u}_{2}\right):$ | 1 | 0 | $\ldots$ | 1 |

- For $\Omega$ unrestricted, what do we have in $\Omega_{f}$ ? We have:

| $\mathrm{g}:$ | $\mathbf{0}$ | $x_{1}$ | $x_{2}$ | $\mathbf{1}$ |
| :---: | :---: | :---: | :---: | :---: |
| $g\left(\mathbf{u}_{1}\right)$ | 0 | 0 | 1 | 1 |
| $g\left(\mathbf{u}_{2}\right)$ | 0 | 1 | 0 | 1 |
| $F_{1}(g)$ | 0 | 0 | 0 | 1 |
| $F_{2}(g)$ | 0 | 1 | 1 | 1 |
| $F_{3}(g)$ | 1 | 0 | 0 | 1 |
| $F_{4}(g)$ | 1 | 1 | 1 | 1 |

- The rows of the two middle columns have to differ from the first two rows because of requirement 1 .
- The last column contains only ones because of requirement 2 .

## Example - parity cont.

- We need to cover the following four functionals.

| $\mathrm{g}:$ | $\mathbf{0}$ | $x_{1}$ | $x_{2}$ | $\mathbf{1}$ |
| :---: | :---: | :---: | :---: | :---: |
| $g\left(\mathbf{u}_{1}\right)$ | 0 | 0 | 1 | 1 |
| $g\left(\mathbf{u}_{2}\right)$ | 0 | 1 | 0 | 1 |
| $F_{1}(g)$ | 0 | 0 | 0 | 1 |
| $F_{2}(g)$ | 0 | 1 | 1 | 1 |
| $F_{3}(g)$ | 1 | 0 | 0 | 1 |
| $F_{4}(g)$ | 1 | 1 | 1 | 1 |

## Example - parity cont.

- We need to cover the following four functionals.

| $g:$ | $\mathbf{0}$ | $x_{1}$ | $x_{2}$ | $\mathbf{1}$ |
| :---: | :---: | :---: | :---: | :---: |
| $g\left(\mathbf{u}_{1}\right)$ | 0 | 0 | 1 | 1 |
| $g\left(\mathbf{u}_{2}\right)$ | 0 | 1 | 0 | 1 |
| $F_{1}(g)$ | 0 | 0 | 0 | 1 |
| $F_{2}(g)$ | 0 | 1 | 1 | 1 |
| $F_{3}(g)$ | 1 | 0 | 0 | 1 |
| $F_{4}(g)$ | 1 | 1 | 1 | 1 |

- $F_{1}$ is covered by $\left(x_{1}, x_{2}, \vee\right)$, since $F_{1}\left(x_{1}\right) \vee F_{1}\left(x_{2}\right)=0$, but $F_{1}\left(x_{1} \vee x_{2}\right)=F_{1}(\mathbf{1})=1$

## Example - parity cont.

- We need to cover the following four functionals.

| $g:$ | $\mathbf{0}$ | $x_{1}$ | $x_{2}$ | $\mathbf{1}$ |
| :---: | :---: | :---: | :---: | :---: |
| $g\left(\mathbf{u}_{1}\right)$ | 0 | 0 | 1 | 1 |
| $g\left(\mathbf{u}_{2}\right)$ | 0 | 1 | 0 | 1 |
| $F_{1}(g)$ | 0 | 0 | 0 | 1 |
| $F_{2}(g)$ | 0 | 1 | 1 | 1 |
| $F_{3}(g)$ | 1 | 0 | 0 | 1 |
| $F_{4}(g)$ | 1 | 1 | 1 | 1 |

- $F_{1}$ is covered by $\left(x_{1}, x_{2}, \vee\right)$, since $F_{1}\left(x_{1}\right) \vee F_{1}\left(x_{2}\right)=0$, but $F_{1}\left(x_{1} \vee x_{2}\right)=F_{1}(1)=1$
- $F_{2}$ is covered by $\left(x_{1}, x_{2}, \wedge\right)$, since $F_{2}\left(x_{1}\right) \wedge F_{2}\left(x_{2}\right)=1$, but $F_{2}\left(x_{1} \wedge x_{2}\right)=F_{2}(\mathbf{0})=0$

## Example - parity cont.

- We need to cover the following four functionals.

| $g:$ | $\mathbf{0}$ | $x_{1}$ | $x_{2}$ | $\mathbf{1}$ |
| :---: | :---: | :---: | :---: | :---: |
| $g\left(\mathbf{u}_{1}\right)$ | 0 | 0 | 1 | 1 |
| $g\left(\mathbf{u}_{2}\right)$ | 0 | 1 | 0 | 1 |
| $F_{1}(g)$ | 0 | 0 | 0 | 1 |
| $F_{2}(g)$ | 0 | 1 | 1 | 1 |
| $F_{3}(g)$ | 1 | 0 | 0 | 1 |
| $F_{4}(g)$ | 1 | 1 | 1 | 1 |

- $F_{1}$ is covered by $\left(x_{1}, x_{2}, \vee\right)$, since $F_{1}\left(x_{1}\right) \vee F_{1}\left(x_{2}\right)=0$, but $F_{1}\left(x_{1} \vee x_{2}\right)=F_{1}(\mathbf{1})=1$
- $F_{2}$ is covered by $\left(x_{1}, x_{2}, \wedge\right)$, since $F_{2}\left(x_{1}\right) \wedge F_{2}\left(x_{2}\right)=1$, but $F_{2}\left(x_{1} \wedge x_{2}\right)=F_{2}(\mathbf{0})=0$
- $F_{3}$ is covered by $\left(x_{1},-, \neg\right)$, since $\neg F_{3}\left(x_{1}\right)=1$, but $F_{3}\left(\neg x_{1}\right)=F_{3}\left(x_{2}\right)=0$ and so is $F_{4}$

## Example - parity cont.

- We need to cover the following four functionals.

| $g:$ | $\mathbf{0}$ | $x_{1}$ | $x_{2}$ | $\mathbf{1}$ |
| :---: | :---: | :---: | :---: | :---: |
| $g\left(\mathbf{u}_{1}\right)$ | 0 | 0 | 1 | 1 |
| $g\left(\mathbf{u}_{2}\right)$ | 0 | 1 | 0 | 1 |
| $F_{1}(g)$ | 0 | 0 | 0 | 1 |
| $F_{2}(g)$ | 0 | 1 | 1 | 1 |
| $F_{3}(g)$ | 1 | 0 | 0 | 1 |
| $F_{4}(g)$ | 1 | 1 | 1 | 1 |

- $F_{1}$ is covered by $\left(x_{1}, x_{2}, \vee\right)$, since $F_{1}\left(x_{1}\right) \vee F_{1}\left(x_{2}\right)=0$, but $F_{1}\left(x_{1} \vee x_{2}\right)=F_{1}(\mathbf{1})=1$
- $F_{2}$ is covered by $\left(x_{1}, x_{2}, \wedge\right)$, since $F_{2}\left(x_{1}\right) \wedge F_{2}\left(x_{2}\right)=1$, but $F_{2}\left(x_{1} \wedge x_{2}\right)=F_{2}(\mathbf{0})=0$
- $F_{3}$ is covered by $\left(x_{1},-, \neg\right)$, since $\neg F_{3}\left(x_{1}\right)=1$, but $F_{3}\left(\neg x_{1}\right)=F_{3}\left(x_{2}\right)=0$ and so is $F_{4}$
- This is the smallest possible cover using OP, therefore the lower bound is $2+3=5$.

## Quality of the lower bound

- Why should we consider $\Omega$ restricted to some type of functionals?

## Quality of the lower bound

- Why should we consider $\Omega$ restricted to some type of functionals?
- Full $\Omega$ is huge, $|\Omega|=2^{2|U|}$ and $|U|=\mathcal{O}\left(2^{n}\right)$. So covering only part of it can be much more managable.

## Quality of the lower bound

- Why should we consider $\Omega$ restricted to some type of functionals?
- Full $\Omega$ is huge, $|\Omega|=2^{2^{|U|}}$ and $|U|=\mathcal{O}\left(2^{n}\right)$. So covering only part of it can be much more managable.
- While considering unrestricted $\Omega$ we can obtain a larger lower bound. However in some situations for some restrictions we get the following theorem:

## Meta-Converse

Theorem (Meta-Converse)
There is a program $P$ over OP that computes $f$ that is not much larger than $\rho(f)$.

## Meta-Converse

Theorem (Meta-Converse)
There is a program $P$ over OP that computes $f$ that is not much larger than $\rho(f)$.

Proof.
(sketch) We have a cover $C=\left\{\left(g_{1}, h_{1}, \circ_{1}\right), \ldots,\left(g_{t}, h_{t}, \circ_{t}\right)\right\}$.

## Meta-Converse

Theorem (Meta-Converse)
There is a program $P$ over OP that computes $f$ that is not much larger than $\rho(f)$.

Proof.
(sketch) We have a cover $C=\left\{\left(g_{1}, h_{1}, \circ_{1}\right), \ldots,\left(g_{t}, h_{t}, \circ_{t}\right)\right\}$.

## Meta-Converse

Theorem (Meta-Converse)
There is a program $P$ over OP that computes $f$ that is not much larger than $\rho(f)$.

## Proof.

(sketch) We have a cover $C=\left\{\left(g_{1}, h_{1}, \circ_{1}\right), \ldots,\left(g_{t}, h_{t}, \circ_{t}\right)\right\}$. This is not a program, and our task is to "organize" these unrelated gates into a program.

## Meta-Converse

Theorem (Meta-Converse)
There is a program $P$ over OP that computes $f$ that is not much larger than $\rho(f)$.

## Proof.

(sketch) We have a cover $C=\left\{\left(g_{1}, h_{1}, \circ_{1}\right), \ldots,\left(g_{t}, h_{t}, \circ_{t}\right)\right\}$. This is not a program, and our task is to "organize" these unrelated gates into a program.

Claim: $f(z)=1 \Leftrightarrow \exists F \in \Omega$ that defines $z$ and is not covered with $C$.

## Meta-Converse

## Theorem (Meta-Converse)

There is a program $P$ over OP that computes $f$ that is not much larger than $\rho(f)$.

## Proof.

(sketch) We have a cover $C=\left\{\left(g_{1}, h_{1}, \circ_{1}\right), \ldots,\left(g_{t}, h_{t}, \circ_{t}\right)\right\}$. This is not a program, and our task is to "organize" these unrelated gates into a program.

Claim: $f(z)=1 \Leftrightarrow \exists F \in \Omega$ that defines $z$ and is not covered with $C$. proof of the claim: For " $\Rightarrow$ " pick $F_{z}(g):=g(z)$. This is by definition compatible with every operation.

## Meta-Converse

## Theorem (Meta-Converse)

There is a program $P$ over OP that computes $f$ that is not much larger than $\rho(f)$.

## Proof.

(sketch) We have a cover $C=\left\{\left(g_{1}, h_{1}, \circ_{1}\right), \ldots,\left(g_{t}, h_{t}, \circ_{t}\right)\right\}$. This is not a program, and our task is to "organize" these unrelated gates into a program.

Claim: $f(z)=1 \Leftrightarrow \exists F \in \Omega$ that defines $z$ and is not covered with $C$. proof of the claim: For " $\Rightarrow$ " pick $F_{z}(g):=g(z)$. This is by definition compatible with every operation.
" $\Leftarrow$ " has been already proven as a part of the Main theorem. $\square$

## Meta-Converse

## Theorem (Meta-Converse)

There is a program $P$ over OP that computes $f$ that is not much larger than $\rho(f)$.

## Proof.

(sketch) We have a cover $C=\left\{\left(g_{1}, h_{1}, \circ_{1}\right), \ldots,\left(g_{t}, h_{t}, \circ_{t}\right)\right\}$. This is not a program, and our task is to "organize" these unrelated gates into a program.

Claim: $f(z)=1 \Leftrightarrow \exists F \in \Omega$ that defines $z$ and is not covered with $C$. proof of the claim: For " $\Rightarrow$ " pick $F_{z}(g):=g(z)$. This is by definition compatible with every operation.
" $\Leftarrow$ " has been already proven as a part of the Main theorem.
With the claim, we just need to construct a program, that tries to find such $F$. We don't need the whole functional, just its values on $x_{i}$ and the cover. For many choices of OP and $\Omega$ this yields program, that has either linear or polynomial length with respect to $\rho(f)$.

## The choices for $\Omega$

- The following restrictions for $\Omega$ have been considered:

## The choices for $\Omega$

- The following restrictions for $\Omega$ have been considered:
- $\Omega=\{F ; F$ is a filter $\}$, where a filter $F$ is a functional, that is monotone (flipping zeroes in the input can only make the output 1)

## The choices for $\Omega$

- The following restrictions for $\Omega$ have been considered:
- $\Omega=\{F ; F$ is a filter $\}$, where a filter $F$ is a functional, that is monotone (flipping zeroes in the input can only make the output 1)
- $\Omega=\{F ; F$ is a filter $\}$, where a filter $F$ is a functional, that is monotone (flipping zeroes in the input can only make the output 1)

## The unification - Razborov's work

- In 1985 Razborov proved superpolynomial lower bounds on monotone circuit size for the clique and matching functions using his "approximation method"

## The unification - Razborov's work

- In 1985 Razborov proved superpolynomial lower bounds on monotone circuit size for the clique and matching functions using his "approximation method"
- What about lower bounds for non-monotone circuits?

## The unification - Razborov's work

- In 1985 Razborov proved superpolynomial lower bounds on monotone circuit size for the clique and matching functions using his "approximation method"
- What about lower bounds for non-monotone circuits?
- In 1989 Razborov formalized his approximation method and proved it cannot provide superlinear lower bounds for non-monotone circuits.

## The unification - Razborov's work

- In 1985 Razborov proved superpolynomial lower bounds on monotone circuit size for the clique and matching functions using his "approximation method"
- What about lower bounds for non-monotone circuits?
- In 1989 Razborov formalized his approximation method and proved it cannot provide superlinear lower bounds for non-monotone circuits.
- However, he proposed a generalization of this method and proved that it actually characterizes circuit size. So it can be used to prove lower bounds for non-monotone circuits.

## The unification - Razborov's work

- In 1985 Razborov proved superpolynomial lower bounds on monotone circuit size for the clique and matching functions using his "approximation method"
- What about lower bounds for non-monotone circuits?
- In 1989 Razborov formalized his approximation method and proved it cannot provide superlinear lower bounds for non-monotone circuits.
- However, he proposed a generalization of this method and proved that it actually characterizes circuit size. So it can be used to prove lower bounds for non-monotone circuits.
- What we've seen so far is actually his "generalized approximation method", in this point of view, $F$ is seen as an approximation of a gate.

## The unification - Razborov's work

- In 1985 Razborov proved superpolynomial lower bounds on monotone circuit size for the clique and matching functions using his
"approximation method"
- What about lower bounds for non-monotone circuits?
- In 1989 Razborov formalized his approximation method and proved it cannot provide superlinear lower bounds for non-monotone circuits.
- However, he proposed a generalization of this method and proved that it actually characterizes circuit size. So it can be used to prove lower bounds for non-monotone circuits.
- What we've seen so far is actually his "generalized approximation method", in this point of view, $F$ is seen as an approximation of a gate.
- 1990 Razborov proved that somewhat restricted can be associeted with non-deterministic branching programs, an proved a super-linear lower bound for the Majority function.

## The unification - Sipser's work

- On the other hand, in the early 1980's Sipser proposed that we should use infinite analogue of circuits used in topology to guide our intuition.

## The unification - Sipser's work

- On the other hand, in the early 1980's Sipser proposed that we should use infinite analogue of circuits used in topology to guide our intuition.
- We've seen his new proof of separation co-analytic sets from analytic sets.

## The unification - Sipser's work

- On the other hand, in the early 1980's Sipser proposed that we should use infinite analogue of circuits used in topology to guide our intuition.
- We've seen his new proof of separation co-analytic sets from analytic sets.
- $T$ the set of well founded trees is easily co-analytic, but Sipser proved that is it not analytic, by taking a sequence $t_{1}, t_{2}, \cdots \in T$ that converges to $t_{\infty} \notin T$. Which would any analytic circuit would have to accept as well.

## The unification - Sipser's work

- On the other hand, in the early 1980's Sipser proposed that we should use infinite analogue of circuits used in topology to guide our intuition.
- We've seen his new proof of separation co-analytic sets from analytic sets.
- $T$ the set of well founded trees is easily co-analytic, but Sipser proved that is it not analytic, by taking a sequence $t_{1}, t_{2}, \cdots \in T$ that converges to $t_{\infty} \notin T$. Which would any analytic circuit would have to accept as well.
- In his 1984 paper Sipser asks for a finite analogue of a limit that will allow us to carry out such arguments in the finite world.

## The unification - Sipser's work

- On the other hand, in the early 1980's Sipser proposed that we should use infinite analogue of circuits used in topology to guide our intuition.
- We've seen his new proof of separation co-analytic sets from analytic sets.
- $T$ the set of well founded trees is easily co-analytic, but Sipser proved that is it not analytic, by taking a sequence $t_{1}, t_{2}, \cdots \in T$ that converges to $t_{\infty} \notin T$. Which would any analytic circuit would have to accept as well.
- In his 1984 paper Sipser asks for a finite analogue of a limit that will allow us to carry out such arguments in the finite world.
- This should remind us of $\Omega$ a finite notion of a limit, and $F$ a notion of a converging sequence.

## The unification - Karchmer's work

- Karchmeri, in his 1993 paper, was the first one to describe the fusion method in a way that was presented earlier. He observed, that it generalizes the previous efforts.

## The unification - Karchmer's work

- Karchmeri, in his 1993 paper, was the first one to describe the fusion method in a way that was presented earlier. He observed, that it generalizes the previous efforts.
- He noted, that this method can be viewed as a finitary version of an ultraproduct. This idea was pushed even further by Ben-David, Karchmer and Kushilevitz who have showed that standard ultra-filter arguments can simplify Sipser's proof.

## The unification - Karchmer's work cont. 1

- In his 1993 he has also proved three characterization results.

## The unification - Karchmer's work cont. 1

- In his 1993 he has also proved three characterization results.
- First note that here we are considering inputs as both positive and negative literals.

## The unification - Karchmer's work cont. 1

- In his 1993 he has also proved three characterization results.
- First note that here we are considering inputs as both positive and negative literals.
- Choosing $\Omega:=\{F ; F$ is a filter (a monotone functional) $\}$ results in the following characterization of $P$ :

## The unification - Karchmer's work cont. 1

- In his 1993 he has also proved three characterization results.
- First note that here we are considering inputs as both positive and negative literals.
- Choosing $\Omega:=\{F ; F$ is a filter (a monotone functional) $\}$ results in the following characterization of $P$ :

Theorem (Characterization of $\mathbf{P}$ )
$f \in \boldsymbol{P}$ if and only if $\rho\left(\Omega_{f}\right) \leq p(n)$ for some polynomial $p$.

## The unification - Karchmer's work cont. 2

- Now consider: $\Omega^{\prime}:=\{F ; F$ a self dual filter $\}$, that is a set of filters, that contain each string or its negation.

## The unification - Karchmer's work cont. 2

- Now consider: $\Omega^{\prime}:=\{F ; F$ a self dual filter $\}$, that is a set of filters, that contain each string or its negation.
- Note that $\Omega^{\prime}$ contains more than just ultrafilters.

## The unification - Karchmer's work cont. 2

- Now consider: $\Omega^{\prime}:=\{F ; F$ a self dual filter $\}$, that is a set of filters, that contain each string or its negation.
- Note that $\Omega^{\prime}$ contains more than just ultrafilters.
- We have the following result:

## The unification - Karchmer's work cont. 2

- Now consider: $\Omega^{\prime}:=\{F ; F$ a self dual filter $\}$, that is a set of filters, that contain each string or its negation.
- Note that $\Omega^{\prime}$ contains more than just ultrafilters.
- We have the following result:

## Theorem (Characterization of NP)

$f \in \mathbf{N P}$ if and only if $\rho\left(\Omega_{f}^{\prime}\right) \leq p(n)$ for some polynomial $p$.

## The unification - Karchmer's work cont. 3

- Again choosing $\Omega:=\{F ; F$ is a filter (a monotone functional) $\}$, but restricting inputs to positive literals, results in the following characterization:

## The unification - Karchmer's work cont. 3

- Again choosing $\Omega:=\{F ; F$ is a filter (a monotone functional) $\}$, but restricting inputs to positive literals, results in the following characterization:

```
Theorem (Characterization of mP)
f\inmP if and only if }\mp@subsup{\rho}{+}{}(\mp@subsup{\Omega}{f}{})\leqp(n)\mathrm{ for some polynomial p.
```

## The unification - Karchmer's work cont. 3

- Again choosing $\Omega:=\{F ; F$ is a filter (a monotone functional) $\}$, but restricting inputs to positive literals, results in the following characterization:

```
Theorem (Characterization of mP)
f\inm\boldsymbol{P}\mathrm{ if and only if }\mp@subsup{\rho}{+}{}(\mp@subsup{\Omega}{f}{\prime})\leqp(n) for some polynomial p.
```

- Karchmer used this to give a new proof of Razborov's super-polynomial lower bound for the monotone clique.

## Algebraic variants

- $\left(\{0,1\}^{n}, \wedge, \vee,(\neg)\right)$ are precisely finite Boolean algebras, and a filter is a natural notion for these structures, that can give some intuition on the choice $\Omega=\{$ filters $\}$

## Algebraic variants

- $\left(\{0,1\}^{n}, \wedge, \vee,(\neg)\right)$ are precisely finite Boolean algebras, and a filter is a natural notion for these structures, that can give some intuition on the choice $\Omega=\{$ filters $\}$
- $\left(\{0,1\}^{n}, \wedge, \oplus\right)$ are precisely finite arithmetical vector spaces over GF(2), what is a "natural" choice for $\Omega$ here?

## Algebraic variants

- $\left(\{0,1\}^{n}, \wedge, \vee,(\neg)\right)$ are precisely finite Boolean algebras, and a filter is a natural notion for these structures, that can give some intuition on the choice $\Omega=\{$ filters $\}$
- $\left(\{0,1\}^{n}, \wedge, \oplus\right)$ are precisely finite arithmetical vector spaces over GF(2), what is a "natural" choice for $\Omega$ here?

## Algebraic variants
