ヘロト 人間 ト 人 ヨト 人 ヨトー

Classic structure theory: direct sum decompositions

A class of modules C is decomposable, provided that there is a cardinal κ such that each module in C is a direct sum of strongly $< \kappa$ -presented modules from C.

[Kaplansky]

1. The class \mathcal{P}_0 of all projective modules is decomposable.

[Faith-Walker]

2. The class \mathcal{I}_0 of all injective modules is decomposable iff R is a right noetherian ring.

[Huisgen-Zimmermann]

3. Mod-R is decomposable iff R is a right pure-semisimple ring. In fact, if M is a module such that Prod(M) is decomposable, then M is Σ -pure-injective. Such examples, however, are rare in general – most classes of modules are not decomposable.

Example

Assume that the ring R is not right perfect, that is, there is a strictly decreasing chain of principal left ideals

$$Ra_0 \supseteq \cdots \supseteq Ra_n \dots a_0 \supseteq Ra_{n+1}a_n \dots a_o \supseteq \dots$$

Then the class \mathcal{F}_0 of all flat modules is not decomposable.

Example

There exist arbitrarily large indecomposable flat abelian groups.

- 4 同 6 4 日 6 4 日 6

Transfinite extensions

Let $\mathcal{A} \subseteq \text{Mod}-R$. A module M is \mathcal{A} -filtered (or a transfinite extension of the modules in \mathcal{A}), provided that there exists an increasing sequence $(M_{\alpha} \mid \alpha \leq \sigma)$ consisting of submodules of M such that $M_0 = 0$, $M_{\sigma} = M$, • $M_{\alpha} = \bigcup_{\beta \leq \alpha} M_{\beta}$ for each limit ordinal $\alpha \leq \sigma$, and

• for each $\alpha < \sigma$, $M_{\alpha+1}/M_{\alpha}$ is isomorphic to an element of A.

Notation: $M \in Filt(\mathcal{A})$. A class \mathcal{A} is filtration closed if $Filt(\mathcal{A}) = \mathcal{A}$.

Eklof Lemma

 $^{\perp}\mathcal{C} = \text{KerExt}^{1}_{R}(-,\mathcal{C})$ is filtration closed for each class of modules \mathcal{C} .

In particular, so are the classes \mathcal{P}_n and \mathcal{F}_n of all modules of projective and flat dimension $\leq n$, for each $n < \omega$.

Deconstructible classes

A class of modules \mathcal{A} is deconstructible, provided there is a cardinal κ such that $\mathcal{A} = \operatorname{Filt}(\mathcal{A}^{<\kappa})$ where $\mathcal{A}^{<\kappa}$ denotes the class of all strongly $< \kappa$ -presented modules from \mathcal{A} .

All decomposable classes are deconstructible.

For each $n < \omega$, the classes \mathcal{P}_n and \mathcal{F}_n are deconstructible.

[Eklof-T.]

More in general, for each set of modules S, the class $^{\perp}(S^{\perp})$ is deconstructible. Here, $S^{\perp} = \text{KerExt}_{R}^{1}(S, -)$.

イロト 不得下 イヨト イヨト 二日

Approximations for relative homological algebra

A class of modules \mathcal{A} is precovering if for each module M there is $f \in \operatorname{Hom}_R(A, M)$ with $A \in \mathcal{A}$ such that each $f' \in \operatorname{Hom}_R(A', M)$ with $A' \in \mathcal{A}$ factorizes through f:

The map f is an \mathcal{A} -precover of M.

If f is moreover right minimal (that is, f factorizes through itself only by an automorphism of A), then f is an A-cover of M.

If \mathcal{A} provides for covers for all modules, then \mathcal{A} is called a covering class.

The abundance of approximations

[Enochs], [Šťovíček]

- All deconstructible classes are precovering.
- All precovering classes closed under direct limits are covering.

In particular, the class $^{\perp}(S^{\perp})$ is precovering for any set of modules S. *Note:* If $R \in S$, then $^{\perp}(S^{\perp})$ coincides with the class of all direct summands of S-filtered modules.

Flat cover conjecture

 \mathcal{F}_0 is covering for any ring R, and so are the classes \mathcal{F}_n for each n > 0.

```
The classes \mathcal{P}_n (n \ge 0) are precovering. ...
```

イロト イポト イヨト イヨト

Bass modules

Let *R* be a ring and *C* be a class of countably presented modules. $\lim_{\omega} C$ denotes the class of all Bass modules over *C*, that is, the modules *B* that are countable direct limits of modules from *C*. W.l.o.g., such *B* is the direct limit of a chain

$$F_0 \xrightarrow{f_0} F_1 \xrightarrow{f_1} \ldots \xrightarrow{f_{i-1}} F_i \xrightarrow{f_i} F_{i+1} \xrightarrow{f_{i+1}} \ldots$$

with $F_i \in C$ and $f_i \in \operatorname{Hom}_R(F_i, F_{i+1})$ for all $i < \omega$.

The classic Bass module

Let C be the class of all countably generated projective modules. Then the Bass modules coincide with the countably presented flat modules. If R is not right perfect, then a classic instance of such a Bass module B arises when $F_i = R$ and f_i is the left multiplication by a_i ($i < \omega$) where $Ra_0 \supseteq \cdots \supseteq Ra_n \ldots a_0 \supseteq Ra_{n+1}a_n \ldots a_o \supseteq \ldots$ is strictly decreasing.

Flat Mittag-Leffler modules

[Raynaud-Gruson]

A module *M* is flat Mittag-Leffler provided the functor $M \otimes_R -$ is exact, and for each system of left *R*-modules $(N_i | i \in I)$, the canonical map $M \otimes_R \prod_{i \in I} N_i \to \prod_{i \in I} M \otimes_R N_i$ is monic.

The class of all flat Mittag-Lefler modules is denoted by \mathcal{FM} .

 $\mathcal{P}_0 \subseteq \mathcal{FM} \subseteq \mathcal{F}_0.$ \mathcal{FM} is filtration closed, and it is closed under pure submodules.

[Raynaud-Gruson]

 $M \in \mathcal{FM}$, iff each countable subset of M is contained in a countably generated projective and pure submodule of M. In particular, all countably generated modules in \mathcal{FM} are projective.

Theorem (Angeleri-Šaroch-T.)

Assume that R is not right perfect. Then the class \mathcal{FM} is not precovering, and hence not deconstructible.

Idea of proof: Choose a non-projective Bass module *B* over $\mathcal{P}_0^{<\omega}$, and prove that *B* has no \mathcal{FM} -precover.

The main tool: Tree modules.

II. Tree modules and their applications

The trees

Let κ be an infinite cardinal, and T_{κ} be the set of all finite sequences of ordinals $< \kappa$, so

$$T_{\kappa} = \{\tau : \mathbf{n} \to \kappa \mid \mathbf{n} < \omega\}.$$

Partially ordered by inclusion, T_{κ} is a tree, called the tree on κ .

Let $Br(T_{\kappa})$ denote the set of all branches of T_{κ} . Each $\nu \in Br(T_{\kappa})$ can be identified with an ω -sequence of ordinals $< \kappa$:

$$\mathsf{Br}(T_{\kappa}) = \{\nu : \omega \to \kappa\}.$$

 $|T_{\kappa}| = \kappa$ and $|Br(T_{\kappa})| = \kappa^{\omega}$.

Notation: $\ell(\tau)$ denotes the length of τ for each $\tau \in T_{\kappa}$.

イロト イポト イヨト イヨト

Decorating trees by Bass modules

Let
$$D := \bigoplus_{\tau \in T_{\kappa}} F_{\ell(\tau)}$$
, and $P := \prod_{\tau \in T_{\kappa}} F_{\ell(\tau)}$.

For $\nu \in Br(T_{\kappa})$, $i < \omega$, and $x \in F_i$, we define $x_{\nu i} \in P$ by

 $\pi_{\nu \upharpoonright i}(x_{\nu i}) = x,$

$$\pi_{\nu \upharpoonright j}(x_{\nu i}) = g_{j-1} \dots g_i(x) \text{ for each } i < j < \omega,$$

 $\pi_{\tau}(x_{\nu i}) = 0$ otherwise,

where $\pi_{\tau} \in \operatorname{Hom}_{R}(P, F_{\ell(\tau)})$ denotes the τ th projection for each $\tau \in T_{\kappa}$.

Let $X_{\nu i} := \{x_{\nu i} \mid x \in F_i\}$. Then $X_{\nu i}$ is a submodule of P isomorphic to F_i .

Jan Trlifaj (Univerzita Karlova, Praha)

イロト イポト イヨト イヨト 二日

The tree modules

Let
$$X_{\nu} := \sum_{i < \omega} X_{\nu i}$$
, and $\mathbf{G} := \sum_{\nu \in \mathsf{Br}(\mathcal{T}_{\kappa})} X_{\nu}$.

Basic properties

• $D \subseteq G \subseteq P$.

• There is a 'tree module' exact sequence

$$0 \to D \to G \to B^{(\mathsf{Br}(\tau_{\kappa}))} \to 0.$$

• *G* is a flat Mittag-Leffler module.

э

(人間) トイヨト イヨト

Proof of the Theorem

Assume there exists a \mathcal{FM} -precover $f : F \to B$ of the classic Bass module B. Let K = Ker(f), so we have an exact sequence

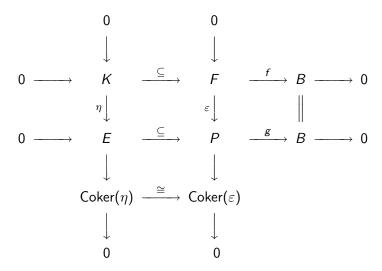

$$0 \to K \hookrightarrow F \xrightarrow{f} B \to 0.$$

Let κ be an infinite cardinal such that $|R| \leq \kappa$ and $|K| \leq 2^{\kappa} = \kappa^{\omega}$. Consider the 'tree module' exact sequence

$$0 \to D \hookrightarrow G \to B^{(2^{\kappa})} \to 0$$

so $G \in \mathcal{FM}$ and D is a free module of rank κ . Clearly, $G \in \mathcal{P}_1$. Let $\eta : K \to E$ be a $\{G\}^{\perp}$ -preenvelope of K with a $\{G\}$ -filtered cokernel.

Consider the pushout

Then $P \in \mathcal{FM}$. Since f is an \mathcal{FM} -precover, there exists $h : P \to F$ such that fh = g. Then $f = g\varepsilon = fh\varepsilon$, whence K + Im(h) = F. Let $h' = h \upharpoonright E$. Then $h' : E \to K$ and $\text{Im}(h') = K \cap \text{Im}(h)$.

Consider the restricted exact sequence

$$0 \longrightarrow \operatorname{Im}(h') \xrightarrow{\subseteq} \operatorname{Im}(h) \xrightarrow{f \upharpoonright \operatorname{Im}(h)} B \longrightarrow 0$$

As $E \in G^{\perp}$ and $G \in \mathcal{P}_1$, also $\mathsf{Im}(h') \in G^{\perp}$.

Applying $\text{Hom}_{R}(-, \text{Im}(h'))$ to the 'tree-module' exact sequence above, we obtain the exact sequence

$$\operatorname{Hom}_R(D,\operatorname{Im}(h')) \to \operatorname{Ext}^1_R(B,\operatorname{Im}(h'))^{2^{\kappa}} \to 0$$

where the first term has cardinality only $\leq |K|^\kappa \leq 2^\kappa$, so the second term must be zero.

This yields $Im(h') \in B^{\perp}$. Then $f \upharpoonright Im(h)$ splits, and so does the \mathcal{FM} -precover f, a contradiction with $B \notin \mathcal{FM}$.

▲日▼ ▲冊▼ ▲ヨ▼ ▲ヨ▼ ヨー つぬる

Lemma (Šaroch)

Let C be a class of countably presented modules, and \mathcal{L} the class of all 'locally C-free' modules.

Let B be a Bass module over C such that B is not a direct summand in a module from \mathcal{L} .

Then B has no *L*-precover.

III. A generalization via tilting theory

э

イロト イポト イヨト イヨト

Large tilting modules

- T is a (large) tilting module provided that
 - T has finite projective dimension,
 - $\operatorname{Ext}^{i}_{R}(T, T^{(\kappa)}) = 0$ for each cardinal κ , and
 - there exists an exact sequence 0 → R → T₀ → · · · → T_r → 0 such that r < ω, and for each i < r, T_i ∈ Add(T), i.e., T_i is a direct summand of a (possibly infinite) direct sum of copies of T.

$$\mathcal{B} = \{T\}^{\perp_{\infty}} = \bigcap_{1 < i} \operatorname{KerExt}_{R}^{i}(T, -) \text{ the right tilting class of } T.$$

$$\mathcal{A} = {}^{\perp}\mathcal{B} \text{ the left tilting class of } T.$$

- $\mathcal{A} \cap \mathcal{B} = \operatorname{Add}(T)$.
- Right tilting classes coincide with the classes of finite type, that is, they have the form S[⊥] where S is a set of strongly finitely presented modules of bounded projective dimension.

• $\mathcal{A} = \mathsf{Filt}(\mathcal{A}^{\leq \omega})$, hence \mathcal{A} is precovering. Moreover, $\mathcal{A} \subseteq \varinjlim \mathcal{A}^{<\omega}$. Jan Trilfaj (Univerzita Karlova, Praha) Set-theoretic homological algebra

$\Sigma\text{-pure split tilting modules}$

A module M is Σ -pure split provided that each pure embedding $N' \hookrightarrow N$ with $N \in Add(M)$ splits.

[Angeleri-T.]

A tilting module \mathcal{T} is Σ -pure split, iff $\mathcal{A} = \varinjlim \mathcal{A}^{<\omega}$, iff \mathcal{A} closed under direct limits.

Examples

Let T = R. Then T is a tilting module of projective dimension 0, and T is Σ -pure split iff R is a right perfect ring.

Each Σ -pure injective tilting module is Σ -pure split. Each finitely generated tilting module over any artin algebra is Σ -pure injective.

Locally *T*-free modules

Let R be a ring and T a tilting module.

A module M is locally T-free provided that M possesses a set \mathcal{H} of submodules such that

- $\mathcal{H} \subseteq \mathcal{A}^{\leq \omega}$,
- each countable subset of M is contained in an element of \mathcal{H} ,
- \mathcal{H} is closed under unions of countable chains.

Let \mathcal{L} denote the class of all locally T-free modules.

Note: If *M* is countably generated, then *M* is locally *T*-free, iff $M \in \mathcal{A}^{\leq \omega}$.

イロト 不得 とくまとう まし

For any ring R and any tilting module T, we have

 $\mathcal{A} \subseteq \mathcal{L} \subseteq \varinjlim \mathcal{A}^{<\omega}.$

The 0-dimensional case

Let R be an arbitrary ring and T = R. Then

$$\mathcal{A} = \mathcal{P}_0 \subseteq \mathcal{L} = \mathcal{F}\mathcal{M} \subseteq \varinjlim \mathcal{A}^{<\omega} = \mathcal{F}_0.$$

イロト 不得 トイヨト イヨト

Locally T-free modules and approximations

Theorem

Let R be a ring and T be a tilting module. Then TFAE:

- *L* is (pre)covering.
- **2** \mathcal{L} is deconstructible.
- **3** T is Σ -pure split.

Note: The theorem on flat Mittag-Leffler modules stated earlier is just the particular case of T = R.

・ 何 ト ・ ヨ ト ・ ヨ ト

The role of Bass modules, and Enochs' Conjecture

Theorem

 \mathcal{L} is (pre)covering, iff \mathcal{A} is closed under direct limits, iff $B \in \mathcal{A}$ for each Bass module B over $\mathcal{A}^{<\omega}$ (i.e., $\lim_{\omega \to \omega} (\mathcal{A}^{<\omega}) \subseteq \mathcal{A}$).

Enochs' Conjecture

Let C be a class of modules. Then C is covering, iff C is precovering and closed under direct limits.

Corollary

The Enochs' Conjecture holds for all left tilting classes of modules.

イロト 人間ト イヨト イヨト

A finite dimensional example

Let R be an indecomposable hereditary finite dimensional algebra of infinite representation type.

Then there is a partition of ind-R into three sets:

- $q \dots$ the indecomposable preinjective modules
- *p* ... the indecomposable preprojective modules
- $t \dots$ the regular modules (the rest).

Then p^{\perp} is a right tilting class (and $M \in p^{\perp}$, iff M has no non-zero direct summands from p).

The tilting module T inducing p^{\perp} is called the Lukas tilting module. The left tilting class of T is the class of all Baer modules. The locally T-free modules are called locally Baer modules.

イロト 不得 トイヨト イヨト

Non-precovering classes of locally Baer modules

Theorem

- The class of all Baer modules coincides with Filt(p).
- The Lukas tilting module T is countably generated, but has no finite dimensional direct summands, and it is not Σ-pure split.
 So the class L is not precovering (and hence not deconstructible).

The Bass modules behind the scene

The relevant Bass modules can be obtained as unions of the chains

$$P_0 \stackrel{f_0}{\hookrightarrow} P_1 \stackrel{f_1}{\hookrightarrow} \dots \stackrel{f_{i-1}}{\hookrightarrow} P_i \stackrel{f_i}{\hookrightarrow} P_{i+1} \stackrel{f_{i+1}}{\hookrightarrow} \dots$$

such that all the P_i are preprojective (i.e., in add(p)), but the cokernels of all the f_i are regular (i.e., in add(t)).

Almost split maps and sequences

Definition

Let *R* be a ring and *N* be a module. A morphism of modules $f : M \to N$ is right almost split, provided that the following are equivalent for each morphism $g : P \to N$:

- g factorizes through f,
- g is not a split epimorphism.

Dually, left almost split morphisms $f': N' \rightarrow M'$ are defined.

A short exact sequence of modules $0 \rightarrow N' \xrightarrow{f'} M \xrightarrow{f} N \rightarrow 0$ is almost split, if f and f' are right and left almost split morphisms, respectively.

Theorem (Auslander)

Let N be an (indecomposable) finitely presented module with local endomorphism ring. Then there exists a right almost split morphism $f: M \rightarrow N$. If N is not projective, then there even exists an almost split sequence as above. Jan Trlifaj (Univerzita Karlova, Praha) Set-theoretic homological algebra 30

Auslander's problem and generalized tree modules

Auslander'1975, in Proc. 2nd Conf. Univ. Oklahoma

Are there further examples of right almost split morphisms in Mod-R?

A negative answer has recently been given using (generalized) tree modules:

Theorem (Šaroch'2015)

Let R be a ring and N be a module. TFAE:

- **()** There exists a right almost split morphism $f: M \to N$.
- **2** *N* is finitely presented, and its endomorphism ring is local.

Corollary

Let R be a ring and $0 \rightarrow P \rightarrow M \rightarrow N \rightarrow 0$ be an almost split sequence in Mod-R. Then N is finitely presented with local endomorphism ring, and P is pure-injective.
